## Sampling Theorem

If a signal  $x(t)$  contains no frequency components for frequencies above  $f = W$  hertz, then it is completely described by instantaneous sample values uniformly spaced in time with period  $T_s \leq 1/(2W)$ .

That is, the sampling frequency  $f_s = 1/T_s$  needs to satisfy

$$f_s \geq 2W$$

The frequency  $2W$  is referred to as the *Nyquist frequency*.

Sampling  
Dilemma

Sampling  
Theory

Sampling  
Theory Proof

Aliasing

Suppose that  $x(t)$  is a continuous-time signal.  $x[n]$  is the discrete-time signal that consists of samples of  $x(t)$  with a sampling period  $T_s$ . Therefore,

$$x[n] = x(nT_s), \quad -\infty < n < \infty.$$

- Suppose that the Fourier transform of  $x(t)$  is  $X(f)$ . That is,

$$X(f) = \mathcal{F}\{x(t)\}.$$

- The continuous-time representation of the sampled signal is

$$\begin{aligned}x_s(t) &= \sum_{n=-\infty}^{\infty} x(nT_s)\delta(t - nT_s) \\ &= x(t) \sum_{n=-\infty}^{\infty} \delta(t - nT_s)\end{aligned}$$

where  $\delta(t)$  is the Dirac delta function.

- The Fourier transform of  $x_s(t)$  is  $X_s(f)$ , which can be calculated as

$$\begin{aligned} X_s(f) = \mathcal{F}\{x_s(t)\} &= X(f) \otimes \mathcal{F}\left\{\sum_{n=-\infty}^{\infty} \delta(t - nT_s)\right\} \\ &= X(f) \otimes \left[f_s \sum_{n=-\infty}^{\infty} \delta(f - nf_s)\right] \\ &= f_s X(f) \otimes \sum_{n=-\infty}^{\infty} \delta(f - nf_s) \\ &= f_s \sum_{n=-\infty}^{\infty} X(f) \otimes \delta(f - nf_s) \\ &= f_s \sum_{n=-\infty}^{\infty} X(f - nf_s) \end{aligned}$$

where,  $f_s = 1/T_s$  is the sampling frequency.

- In order to reconstruct the original signal  $x(t)$ , we need to pass the sampled signal  $x_s(t)$  through an ideal low-pass filter (rectangular function in frequency) to remove the high-frequency replicas.
- A perfect  $X(f)$  can be extracted by applying the rectangular function for filtering only when

$$f_s/2 \geq W$$

where  $W$  is the largest frequency component in signal  $x(t)$ .  $\square$
